Abstract

This review gives concise information about the application of dendrimers as drug delivery carrier in the field of drug delivery. Due to their unique architecture these have improved physical and chemical properties. Due to their terminal groups these show high solubility, miscibility and reactivity. Dendrimers have well defined size, shape, molecular weight and monodispersity. These properties make the dendrimers a suitable carrier in drug delivery application. Dendrimers are unimolecular micelles in nature and due to this enhances the solubility of poorly soluble drugs. Their compatibility with DNA, heparin and polyanions make them more versatile. Dendrimers, also referred as modern day polymers, they offer much more good properties than the conventional polymers. Due to their multivalent and mono disperse character dendrimers have stimulated wide interest in the field of chemistry biology, drug delivery, gene therapy and chemotherapy. Self-assembly produces a faster means of generating nanoscopic functional and structural systems. But their actual utility in drug delivery can be assessed only after deep understanding of factors affecting their properties and their behaviour in vivo.

Keywords: Dendrimers, Drug targeting, nanoscale carriers.

Introduction

Dendrimers are class of well-defined hyper branched synthetic polymer systems, which can be conjugated to various chemical species, such as detection agents, imaging agents, targeting components, biomolecules, pharmaceutical/ therapeutic agents, radio ligands, affinity ligands, for various bioanalytical applications. The term “Dendrimer” arise from two Greek words; “Dendron” meaning tree and “Meros” meaning part. A typical dendrimer structure consists of three basic components: a multi-functional central core moiety where other molecules can be trapped branches units that emanates from the central core and external capping groups. The highly regular branching units are organized in layers called “generations”, and represent the repeating monomer unit of these synthetic macromolecules. Therefore, dendrimers can be synthesized from simple branched monomer units, in a precise and controlled fashion from trunk to branch and to leaf “surface groups”. The three-dimensional structure of dendrimers gives them a variety of unique properties, such as nanoscaled globular shape, well-defined functional groups at the periphery, hydrophobic or hydrophilic cavities in the interior and extremely low polydispersity, and thus a wide range of potential applications.

The precise control over the distribution of drugs is highly valuable to abolish the typical drawbacks of traditional medicine. In recent years, improved pharmacokinetics, biodistribution and controlled release of the drug to the specific targeted site has been achieved with polymer based drug delivery. Unlike traditional polymers, dendrimers have received considerable attention in biological applications due to their high water solubility, biocompatibility, polyvalency and precise molecular weight. These
features make them an ideal carrier for drug delivery and targeting applications. For investigating dendrimers as drug delivery vehicles, their biopermeability across the biological membranes should be considered.

**Application of Dendrimers in Drug delivery for dentistry**

The development of dendrimer based efficient drug delivery systems has attracted a great deal of attention over the last few years. Unlike traditional polymers, dendrimers can be obtained in precise molecular weights even at high generations, which as previously highlighted can provide a reproducible pharmacokinetic behavior. This feature makes them ideal candidates for drug delivery applications. 18, 19

PAMAM dendrimers loaded with calcium and phosphate ions and have been used experimentally to prevent tooth decay. The loaded PAMAM dendrimer was effective for prolonged release of calcium and phosphate at low pH, with neutralization of the acidic environment and inhibition of dental caries. 20

Many potential uses of dendrimer hydrogels (DH) as a drug delivery system in periodontics and implants dentistry as they allow clinicians to customize drug release kinetics, mechanical properties, and in-situ gelling for specific clinical applications. 21

Dendrimer-based dental composites have attracted attention because of the higher cross-link density, decreased water sorption and solubility, improved mechanical properties, and higher resin melting temperature. 22, 23

Triclosan, an effective antimicrobial agent encapsulated into the PAMAM dendrimer resulted in the solubilization of TCN, thus slow release of the drug and improved efficacy. 24

PAMAM dendrimer loaded with different metronidazole concentrations showed prolonged release of the drug, thus proved to be a suitable vehicle for the delivery of antimicrobial drugs at the target site. Hence, it has a relevant application in periodontal therapy. 25

</table>
Dendrimer methyl methacrylate monomers in different dendrimer conjugated resins were 65% and 62% degree of conversion for D12 and D24, respectively.

- Residual monomer contents were 1.0% and 1.5%, respectively for D12 and D24.
- Following photo polymerization, degree of conversion decreased with increase in methyl methacrylate proportion and thus increase in residual monomer content.
- Heat induced polymerization method was suggested as best method with degree of conversion and residual monomers.

| (Tao et al., 2017) | PAMAM dendrimer | G4 | Determination of dentin remineralization extent with PAMAM dendrimer | PAMAM-OH, PAMAM-COOH, PAMAM-NH$_2$ coated dentin | • Dentin coated with PAMAM containing different functional groups showed increased hardness of dentin, reduced loss of mineral and lesion depth, with higher remineralization capability  
• Lower mineral loss and lesion depth with higher dentin tubule blocking effect was shown by PAMAM-COOH, PAMAM-NH$_2$ than PAMAM-OH  
• Effects of PAMAM-COOH, PAMAM-NH$_2$ dentin remineralization were comparable |
| (Xiao et al., 2017) | PAMAM dendrimer | G3 | Development of bioactive multifunctional composite (BMC) via nanoparticles of amorphous calcium phosphate, 2-methacryloyloxyethyl phosphoryl-choline, dimethylamino-hexadecyl methacrylate and silver nanoparticles for class V restoration  
Investigation of BMC with PAMAM dendrimer on remineralization of demineralized root dentin in a cyclic artificial saliva/lactic acid environment for the first time | BMC complex mixture with nanoparticles of amorphous calcium phosphate, 2-methacryloyl-oxyethyl phosphoryl-choline, dimethylamino-hexadecyl methacrylate and silver nanoparticles  
And BMC with PAMAM dendrimer | • PAMAM with BMC showed superior dentin mineralization characteristics  
• The hardness of the dentin increased enough to match healthy root dentin  
• PAMAM with BMC induced complete and effective root dentin remineralization in an acid challenge environment |
| (Ge et al., 2017) | PAMAM dendrimer | G3 | The anti-caries effect and mechanical properties of the modified adhesive in biofilm regulation and remineralization | PAMAM and dimethylaminododecyl methacrylate in biofilm adhesive | • Addition of PAMAM and dimethylaminododecyl methacrylate in adhesive showed no adverse effect on dentin bond strength |
### Conclusion

PAMAM dendrimer has shown to have marked prospective to be used as biomimetic biomaterial for remineralisation of enamel. Addition of dendrimers has shown significant enhancement of mechanical properties of adhesive systems and reduction in polymerization shrinkage of dental composites. It also causes improvement in shear strength and better bonding durability of adhesive systems. Besides drug delivery, dendrimers have been found to have a great emphasis in gene delivery, boron neutron capture therapy, PDT and as magnetic resonance imaging contrast agents. Boosting of commercial applications of dendrimers will not only simplify the treatment of dental problems but also provide new therapeutic options.
